

ABSTRACT OF THE INVENTION

A flexible package with a snap type reclosure. The reclosure has a male part and a female part affixed to the package near the package opening. When the male part and female part are pressed together by the user they interlock with each other and cause the package opening to be substantially held closed. If desired, the snap reclosure may have a locking feature to deter unauthorized opening of the package. If desired, the snap reclosure may also serve as a vent, allowing air to exchange between the inside and outside of the package.
